An antenna component includes an antenna body and a conductor. The antenna body includes a PCB board and a spring piece, and a first end of the spring piece is connected to the PCB board. The conductor is configured to be connected to an insulator and an end metal piece, and includes a first conductive portion opposite to the insulator, and a second conductive portion connected to the first conductive portion and opposite to the end metal piece, and the first conductive portion abuts against a second end of the spring piece. A mobile terminal including an antenna component is further provided.

ABSTRACT

A mobile device includes a first circuit board, a metal frame, an extension radiation element, an electronic component, a second circuit board, and an RF (Radio Frequency) module. The first circuit board includes a system ground plane. The metal frame includes a first portion coupled to the system ground plane. A clearance region is formed between the first portion and the system ground plane. The first portion and the extension radiation element are both coupled to a feeding point. An antenna structure is formed by the first portion and the extension radiation element. The second circuit board is coupled to the electronic component. The electronic component and the second circuit board are both adjacent to the first portion. The RF module is coupled to the feeding point, so as to excite the antenna structure.

ABSTRACT

A Planar Inverted-F antenna (PIFA) device includes a circuit board having a first surface, a second surface, and a through hole, an antenna being disposed in the first surface, and a metal member being disposed in the second surface. The through hole is connected between the first surface and the second surface. The antenna couples with the metal member to have a specific capacitive coupling effect through the through hole to enable transmission and reception of specific wireless frequencies by an electronic device having the PIFA.

ABSTRACT

A multi-antenna communication device is provided, including a grounding conductor plane separating a first side space and a second side space and having a first edge. A four-antenna array including first, second, third and fourth antennas is located at the first edge, and has an overall maximum array length extending along the first edge. The first and second antennas are located in the first side space, and the third and fourth antennas are located in the second side space. Each of the first to fourth antennas includes a feeding conductor line, a grounding conductor line, and a radiating conductor portion electrically connected to a signal source through the feeding conductor line and electrically connected to the first edge through the grounding conductor line, thereby forming a loop path and generating at least one resonant mode. The radiating conductor portion has a corresponding projection line segment at the first edge.

ABSTRACT

An antenna structure includes a first antenna with a first feed point feeding current, a first radiating portion, a second radiating portion, and a first ground point. The first radiating portion is electrically connected to the first feed point and receives radiation signals in a first frequency band. The second radiating portion is electrically connected to the first feed point and receives and sends radiation signals in a second frequency band. The first ground point is spaced apart from the first feed point and is electrically connected to the second radiating portion.

ABSTRACT

An antenna device including a ground conductor and first and second antennas. The first and second antennas are linear antennas and have respective feeding points at ends on a side of the ground conductor. The first and second antennas perform transmission/reception at first and second frequencies that are adjacent to each other, respectively. Moreover, the first antenna includes a first monopole antenna and a loop antenna branched off from the first monopole antenna. An end of the loop antenna opposing a branching point at which the loop antenna is branched off from the first monopole antenna is short-circuited between the feeding points of the first and second antennas on the ground conductor.

(57) **ABSTRACT**

An antenna apparatus includes a ground plane having an edge; a monopole type first antenna element having a first feed point and configured to communicate at a first frequency; and a monopole type second antenna element having a second feed point and configured to communicate at a second frequency, the second antenna element extending from the second feed point in a direction away from the edge. An end portion of the first antenna element is arranged closer to the ground plane than an end portion of the second antenna element is. A length of an interval between the first feed point and the second feed point is in a range of from 0.25-fold to 0.7-fold of an electrical length of a first wavelength at the first frequency. A length of the second antenna element is a length in a range of from 0.15-fold to 0.55-fold of the electrical length.

ABSTRACT

An antenna device includes a slot, a connecting assembly, a first capacitor, a first match circuit, an antenna and a second match circuit. The slot is defined in a shell of the mobile terminal. The slot separates the shell into a first part and a second part. The first part is configured to couple with a mainboard via a first feeding point to form a slot antenna. The connecting assembly connects the first part with the second part. The first capacitor couples the first part and the first feeding point. The first match circuit couples the first capacitor and the first feeding point. The antenna is configured to send a signal through the slot. The antenna is disposed above the mainboard and below the slot and the antenna couples with the mainboard via a second feeding point.

ABSTRACT

A housing assembly for a terminal and a terminal are provided. The housing assembly includes a housing, an antenna radiator and a ferrite. The antenna radiator is positioned at an outer face of the housing, and has a first orthographic projection region on the outer face. The ferrite is arranged on an inner face of the housing, and has a second orthographic projection region on the outer face. The first orthographic projection region is located in the second orthographic projection region.

ABSTRACT(22) Filed: **Sep. 25, 2017**

A miniaturized antenna providing multiband functionality includes a ground portion, a feeder, a first radiator, and a second radiator. The ground portion is grounded. The feeder has a feed end. The feed end can transmit and receive radio frequency (RF) signals. The first radiator is connected to the ground portion. The first radiator and the feeder are spaced apart from each other by a gap. The gap can cause a coupling between the first radiator and the feeder to transmit the RF signal. The second radiator is connected to the first radiator. The second radiator can transmit the RF signal from the first radiator. Multi-band operation is obtained and size of antenna is reduced.

ABSTRACT

The present disclosure relates to a communication method and system for converging a 5th-Generation (5G) communication system for supporting higher data rates beyond a 4th-Generation (4G) system with a technology for Internet of Things (IoT). The present disclosure may be applied to intelligent services based on the 5G communication technology and the IoT-related technology, such as smart home, smart building, smart city, smart car, connected car, health care, digital education, smart retail, security and safety services. A terminal is provided. The terminal includes a metal bezel disposed along an edge of the terminal, an antenna incorporated into the terminal and configured to emit electronic waves, and a beam forming auxiliary unit incorporated into the terminal, separately disposed by a predetermined distance from the antenna, and configured such that the electronic waves emitted from the antenna pass through the metal bezel.

A multiple antenna apparatus is provided. A first feed antenna unit is shared for receiving and transmitting radio frequency (RF) signals corresponding to a bandwidth of a first resonance mode, so as to increase antenna configurable space of the multiple antenna apparatus, and thus a closed slot antenna formed by a wire, a ground plane and a radiation element is able to be configured in the multiple antenna apparatus to receive and transmit the RF signals corresponding to a second resonance mode.

ing to a second resonance mode.

ing to a second resonance mode.

An antenna structure includes a radiating element; a power feeding element configured to feed power to the radiating element in a noncontact manner; a backlight chassis, on which a light source for generating light is attached, a liquid crystal panel being irradiated with the light; and a transmission line conductably connected to the backlight chassis, the power feeding element being connected to an end of the transmission line.

(57) **ABSTRACT**

An electronic device includes a housing. The housing defines a slot and a groove communicating with the slot. The housing is divided into at least a first radiating portion and a second radiating portion by the slot and the groove. The first radiating portion is spaced apart from the second radiating portion. The first radiating portion and the second radiating portion cooperatively serve as an antenna structure of the electronic device to receive and/or transmit wireless signals. The electronic device further performs a predetermined function through the groove.

(57) **ABSTRACT**

The present application provides an antenna system for use in an electronic device. The antenna system includes a conductive substrate having a width, which corresponds to the distance between two opposite side edges of the conductive substrate proximate one end of the device. The antenna system further includes a pair of conductive arms, where each conductive arm in the pair of conductive arms has a connected end, which couples to the conductive substrate at alternative ones of the opposite side edges of the conductive substrate proximate the one end of the device. Each conductive arm further has an open end which extends away from the respective coupled side edge toward the other one of the opposite side edges in a direction of extension. The open ends of the conductive arms in the pair extend toward one another, stopping short of touching or overlapping the other conductive arm in the pair in the direction of extension away from the respective coupled side edge. Correspondingly, a gap is present between the respective open ends of the pair of conductive arms. A signal source is coupled to each of conductive arms proximate the respective open ends of the pair of conductive arms for supplying a signal. The signal source is coupled to at least one of the conductive arms via a respective feed line conductor, where the feed line conductor, that is coupled to the open end of the at least one of the pair of conductive arms, extends in the direction of extension which traverses at least a portion of the gap between the open ends of the conductive arms.

(57) **ABSTRACT**

Embodiments provide mobile device comprising a body frame; processing circuitry affixed to the body frame; a first antenna and a second antenna arranged adjacent to each other in the body frame, the first antenna and the second antenna electrically coupled to the processing circuitry to provide radiation, wherein the first antenna and the second antenna share a common ground defined by the body frame, wherein the first antenna is configured to provide radiation of a first polarization, and wherein the second antenna is configured to provide radiation of a second polarization substantially orthogonal to the first polarization to provide a signal isolation between the first antenna and the second antenna.
